Abstract

Current and temperature measurements from Vector Averaging Current Meters (VACMs) deployed from September 1992 to June 1994 as part of the Deep Basin Experiment (DBE) measuring the trans-equatorial water flow are presented. Salinity and temperature measurements from Conductivity/Temperature/Depth (CTD) casts taken during the mooring deployment and recovery cruises are also presented.

Six mooring sites were occupied with a total of 24 vector averaging current meters and 4 Aanderaa current meters. Three nominal depths (3900, 4100 and 4300 m.) were occupied on each mooring. Three of the 6 moorings had current meters at additional depths.

Basic data from the vector averaging current meters are presented both in statistical tables and graphically as histograms, scatter plots, progressive vector diagrams and spectral diagrams. One day Gaussian filtered plots are shown in composite displays of variables versus time.

Temperature and salinity profiles and θ /S plots for 22 CTD stations are presented.

Acknowledgments

The principal responsibility for the current meter preparations, deployment, and recovery was borne by Scott E. Worrilow. We thank him for outstanding performance of the sensors with over 99% data recovery. Richard Limeburner conducted the data acquisition and processing for both cruises. The quality of the data is superb and we thank him for an excellent job. We also must thank the officers and crew of the R/V Columbus Iselin, Michael Dick, Master, and the officers and crew of the R/V Knorr, Captain Carl F. Swanson, Master, for smooth operations and wonderful cooperation. Research supported by the Division of Ocean Sciences, National Science Foundation grant OCE-9105834.

Preface

This volume is the 46th in a series of technical reports presenting moored current meter and associated data collected by the WHOI Buoy Group.

Associated reports include a data directory and bibliography for the years 1963-1978 which has been published as WHOI technical report 79-88 and a technical memorandum, WHOI-3-88 which describes the WHOI Buoy Group current meter data processing system for VAX /VMS operating system.

Presentation

The printed portion of this report contains introductory text, information about the instruments, data processing procedures, data quality assessments and composite plots of data. Tables and figures give information on moorings, instruments and CTDs.

All of the printed pages are included on the first page of the microfiche. Also included on the first fiche are the cruise reports for the deployment and recovery of the current meter moorings. Pagination of the fiche consists of a three part field, the fiche number, the row letter and the column number.

The second and third pages of fiche present data for the individual current meters. Each row of the fiche presents a different type of display, for instance, statistics are shown in row 'A'. Each column shows the variety of displays for the time series from a single instrument. Figure 1 shows the layout of the three fiche pages. Fiche 2 and 3, shown in the lower panel, have the same layout.

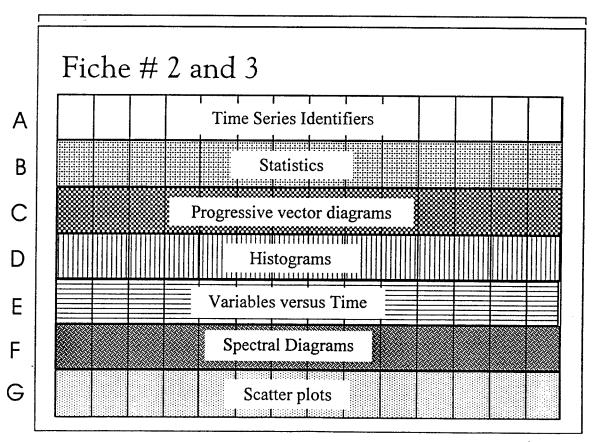

Figure 1 Fiche diagrams

Introduction

This program is a part of the Deep Basin Experiment of the World Ocean Circulation Experiment (WOCE). A description of the overall objectives of the experiment is given by Hogg et al., 1996. The objective of this part of the program was to measure the northward flow of Antarctic Bottom Water (AABW) out of the Brazil Basin in the South Atlantic and into the Guiana Basin in the North Atlantic. A current meter array of six moorings was set for about 600 days across the opening at the Equator between the Brazil Basin and the Guiana Basin west of the Mid-Atlantic Ridge. CTD profiles were taken near each mooring and between mooring locations to measure water properties during the current meter deployment cruise, approximately one month prior to mooring recovery (Smethie, 1996), and during the recovery cruise.

The mooring array was designed to extend in a north-south direction at 36° W with 6 moorings equally spaced between 1° N and 1°30' S (Figure 2). These locations evenly filled the passage between the Brazil and Guiana Basins from north to south, and put the array at approximately the east-west center of the almost perfectly zonal gap that steers the Antarctic Bottom Water. The depths of the Vector Averaging Current Meters (VACMs) were chosen to optimize measurement of the AABW. All six moorings had current meters placed at roughly 3900, 4100 and 4300 meter depths. The two moorings at roughly 1° N and S of the equator each had an additional VACM close to 3300 meters in depth to provide more information about the vertical shear and levels of no motion. One mooring, placed almost exactly on the equator, had VACMs at 2993, 3593 and 4485 meters in addition to the nominal depths mentioned above. Also on the equatorial mooring were four Aanderaa current meters, placed at shallower levels for use by scientists at the Institute für Meereskunde, Kiel, Germany (Fischer and Schott, 1997).

The deployment cruise on R/V Columbus Iselin, cruise CI 92-10, left Bridgetown, Barbados on September 18, 1992 and arrived in Recife, Brazil on October 9, 1992. Six moorings (#936 to #941) with a total of 24 VACMs were deployed. The mooring deployments went as planned for moorings 936, 937 and 939. Mooring 938 anchored about 5 miles west of the planned location due to a strong surface current. The designated location of mooring 940 at 01° 00' S was a little shallower than desired so the mooring was placed about 3 miles NW of the planned location. Mooring 941 was placed near 01° 20' S and 36° 05'W rather than 1° 30' S to place the mooring out of Brazilian waters as the government of Brazil did not grant clearance to deploy within their waters. Eleven CTD stations were taken near and between the mooring positions.

The recovery cruise, from Salvador, Brazil to Bridgetown, Barbados, took place from 27 May to 13 June, 1994 on RV Knorr, cruise 142-4. Every current meter was recovered, although mooring 941 had a failed release, due to a fractured end cap, and had to be recovered by dragging grappling hooks and depressor weights to snag the mooring. As before, a complete bathymetric profile was taken and eleven CTD casts were made at and between each mooring site. The CTD casts at mooring sites were made before mooring recovery so that VACM recorded temperatures and CTD temperature profiles could be compared.

The principal topic of this report will be the graphical displays of up to 610 days of current meter measurements per VACM. In addition, CTD station data plots will be presented.

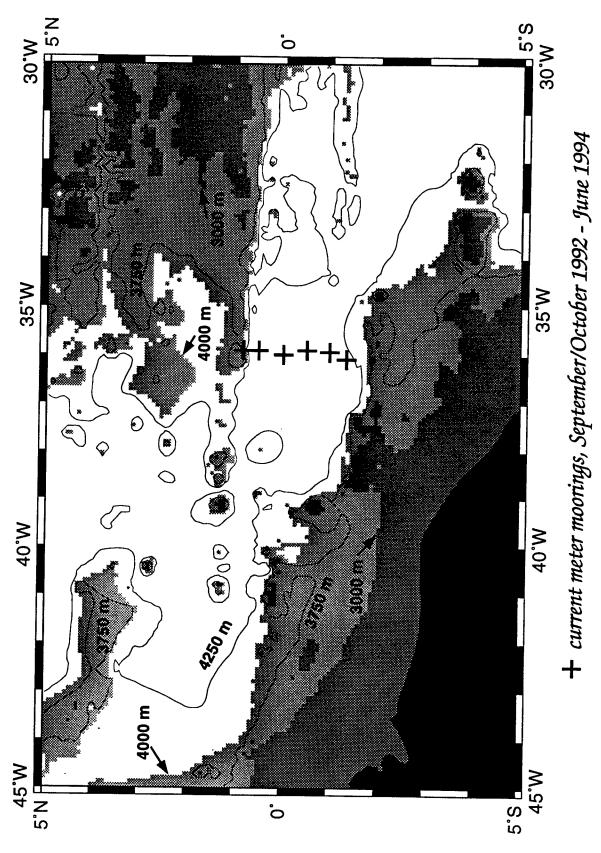

Figure 2 Mooring positions for the Trans-Equatorial water flow

The principal scientific results of the experiment are described by Hall, McCartney and Whitehead (1997) and can be summarized as follows:

- 1) Below θ =1.8° C. an average of 2.0 x 10 ⁶ m ³ sec ⁻¹ of AABW passes westward during the ~600 day array duration.
- 2) The westward AABW flow is persistent and strong at and south of the equator, but north of the equator the AABW flow is weak (neither persistent in direction, nor organized) and is negligible in transport.
- 3) Immediately above the AABW the Lower North Atlantic Deep Water flows strongly eastward in a boundary layer approximately 200 km wide, with eastward flow intensified to the south at the Parnaiba Ridge.
- 4) There is a quasi-annual signal in the AABW transports, with maxima occurring in September/October and minima occurring in February/March. The Lower North Atlantic Deep Water (LNADW) also displays quasi-annual variability, with strong flow episodes in April/May.
- 5) Both the hydrographic surveys and the temperature time series from the moored current meters show that the water below 3900m warms over the observation period (equivalently, isotherms lowered 50 to 80 meters).

Other scientific activities were undertaken on the cruises that set and recovered the moorings. For the cruise of the R/V Columbus Iselin these include the recovery of six SOFAR float listening stations that were part of the 1989-1992 Tropical Atlantic Experiment (Richardson et al., 1994). In addition sixteen RAFOS floats and three sound source moorings were launched as part of the WOCE Deep Basin Experiment (contact B. Owens, N. Hogg at W.H.O.I.). During the R/V Knorr cruise an unsuccessful attempt was made to recover a sediment trap during the steam to Barbados. In addition, the shipboard ADCP was calibrated in shallow waters off Barbados.

CTDs

Conductivity/Temperature/Depth (CTD) profiles were taken in the vicinity of and between each mooring during both the mooring launch and mooring recovery cruises. Table 1 lists the CTD station locations and the associated mooring number.

On the deployment cruise the hydrographic profiles were made using the R/V Iselin's NBIS Mark III CTD underwater unit, an NBIS Mark V deck unit in an 1150 configuration and a General Oceanics Rosette sampling system with 12 ten liter Niskin bottles. An acoustic pinger was used for bottom ranging with depths corrected for sound speed using Matthew's Tables and adding 3m for transducer depth.

The profiles taken on the recovery cruise used an NBIS Mark III underwater unit, an NBIS Mark III deck unit and a General Oceanics 1015 Rosette sampling system with 12 1.2 liter Niskin bottles. A Guildline salinometer was used to calibrate the salinities from the CTD. An acoustic pinger was used for bottom ranging with the depths corrected for sound speed; the corrections were calculated from the CTD data.

The CTD data represent full water column measurements of the temperature and salinity structure of the equatorial system near 36°W. Figures 3 a, b and c show the potential temperature distribution below 3000 meters for the three CTD sections with superimposed current meter locations. Discussions of older hydrographic data at and near this location may be found in articles by McCartney (1993), McCartney and Curry (1993), and Rhein, et al. (1995,1996).

Moorings

Mooring locations are shown in Figure 2. Mooring latitude, longitude, deployment and recovery times are listed in Table 2. The moorings were set and recovered by Scott Worrilow using the R/V Iselin (cruise CI 92-10) from the University of Miami for the deployment cruise and the R/V Knorr (cruise 142-4) from the Woods Hole Oceanographic Institution for the recovery cruise. Mooring 938 was located about 5 miles west of the planned site due to a swift surface countercurrent affecting the deployment. The site for mooring 940 was deliberately shifted due to a bump in the sea floor, and the site for 941 was repositioned to be outside Brazilian waters.

Water depth

Instrument depths

Instruments depths are achieved by determining the water depth at the anticipated anchor launch site, then adding, or deleting, short components of mooring line at the bottom of the mooring string to adjust the overall mooring length (height). The mooring components are all input into program NOYFB (Moller, 1976) which calculates not only the instrument depths but also the buoyancy and mooring performance in different current conditions. Table 4 contains the instrument depths (in meters) for the VACM time series presented in this technical report.

| | Ta | ble 4 | Instrument Placement | | | | | | |
|---------------------|------|-------|----------------------|--------------|--------------|--------------|------|--|--|
| Moori # | ng | | Instr | | | | | | |
| 936 937 | | 3297 | | 3896 3900 | 4096 4100 | 4297 4300 | | | |
| 938 * 939 | 2993 | 3293 | 3593 | 3892 3885 | 4093 4085 | 4292 4285 | 4485 | | |
| 940 941 | | 3307 | | 3907 3899 | 4107 4099 | 4307 4300 | | | |

NOTE: * Four Aanderaa current meters, not described in this report, were included on this mooring at depths of 1293, 1493, 1693, and 1893 meters (Fischer and Schott, 1997)

Vector Averaging Current Meter (VACM)

Vector Averaging Current Meters were developed at WHOI in the early 1970's and were built by EG&G Ocean Products. They use a Savonius rotor to measure current flow, an external vane to measure the instrument's orientation to the current, and an internal compass to measure the instrument's orientation to magnetic north. Temperature is measured with a thermistor mounted in the end cap of the instrument. The VACM uses a crystal-controlled time reference with an accuracy to within one second per day. The 'clock' is synchronized with Universal Temps Coordonne (UTC) before deployment and the accrued error recorded after recovery. The VACM continuously sums vector increments of water flow sensed by the rotor and vane. At regular intervals, for this deployment every half hour, it records on a magnetic tape cassette the accumulated velocity information. The calibration of the VACM and its recording technique were discussed by McCullough (1975). Temperature values are averaged over the entire recording interval for those instruments that do not measure pressure. The instruments that have both a pressure and temperature sensor are multiplexed, that is they time-share the recording interval and average each sensor's input for one half the recording interval. Payne et al. (1976) discussed the accuracy of the temperature measurements. The WHOI temperature sensors were calibrated in the laboratory both before and after deployment. In this deployment several instruments had a pressure sensor which had been left in the instrument from a previous deployment. These shallow water sensors were not changed to deep water sensors as pressure measurements were not required for this experiment.

Current Meter Data Processing

Data from instrument cassettes (VACMs) were read onto a DOS formatted disc. A special interface card in the PC is needed for this transfer. The data were then transferred from the PC disc to a VAX disc in the BUOY format (Maltais, 1969).

Each time series went through a sequence of programs (Tarbell et al., 1988) that checked the time base and converted the data into scientific units. Then the quality of the data was determined (Table 5).

Next the individual variables were edited to remove miscellaneous bad points and the launch and retrieval transients were removed. Finally the Best Basic Version (BBV) was created by linearly interpolating through gaps in the data to make an evenly spaced time series. This series is the basis for all further processing.

Finally a Gaussian filtered series, with a half-width of 24 hours, was created from the BBV and subsampled to have one point a day. The BBV and the Gaussian filtered time series were used to create all the current meter data displays in this report.

Table 5 Current Meter Data quality

| | | | | Three time series versions created - |
| | | | | 9413X1800 - full length - includes gap interp |
| | | | | 9413AC1800 - First 269 days |
| | | | | 9413BC1800 - Last 332 days |

^{#1} Most time series in this set have fewer than 10 time interpolations. Time interpolations (which include the interpolation of all variables) are required when data cycles are missing due to cassette tape reading problems. Interpolating 1000 scattered values in records with over 31,000 data cycles does not appreciably affect the data but is noteworthy as it is unusual.

^{#2} Most instruments had a clock drift of less than a minute over the 600 day deployment period.

Current Meter Temperatures

Thermistors are routinely calibrated in a series of seven temperature baths (0, 5, 10, 15, 20, 25 and 30 degrees) between each deployment. A fit of the temperature to thermistor resistance is derived from the seven bath measurements. The derived parameters (A, B, C's) are then applied to a set of standard resistances (corresponding to the 7 bath temperatures) and yield the numbers in Table 6, below, for thermistor #413. Intercomparison between these values allows the evaluation of the quality and stability of this thermistor.

Similar histories are kept for each thermistor. Payne et al. (1976) described in detail the procedures practiced by the WHOI Buoy Group to achieve the greatest accuracy possible in long term deep ocean thermistor deployments.

Table 6 Example of calibration history - thermistor # 413

| The | rm nui | m ba | th | Temperature differences (in millidegrees) | | | | | | | | |
|-----|--------------|------|------|---|---------------|------|------|------|------|------|--------------|------|

The electronics of each VACM is tuned prior to each deployment to known reference values to increase the accuracy of the temperature measurements.

Current Meter Data Identification

Each time series is identified by a mooring number, a sequential instrument position number, a letter to indicate the data version, and numbers to indicate the sampling rate. Therefore, 9362C1800 identifies data from the second (2) instrument on mooring 936; the version is C, and the sampling rate is one record every 30 minutes (1800 seconds). 9362C1DG24 is a time series that has had a Gaussian filter (G) applied to the data; the filter has a half width of 24 hours (24) and is subsampled once a day (1D).

Descriptions of VACM data displays

There are two different types of plot pages; composite plot pages by depth or by mooring and individual plot pages. Each composite plot page contains data from several different time series. There are 4 composite pages for each of the 6 moorings and 3 composite pages for each of the 3 major instrumented depths (3900m, 4100m, 4300m). The composite plots are either ordered by depth, with the top of the page representing the shallowest time series, or ordered by latitude with the top of the page representing the northernmost time series.

Individual plot pages contain data from one time series. Each individual time series is displayed using histograms, progressive vector diagrams, statistics, variables versus time plots, UV scatter plots and spectral plots.

Histograms (individual)

The histograms were created using MATLAB. An attempt has been made to standardize the plots for the purpose of easier comparisons, instead of letting MATLAB assign parameters to maximize the individual variables presented. The peaks in the histograms at 2 cm/sec reflect a decoding program forced velocity threshold. Histograms are shown on the 2nd and 3rd fiche in row D.

Two histograms (for time series 9401 and 9413) were created from series where the East and North components were not continuous and data values had been interpolated through the gap.

Progressive Vector Diagrams (composite and individual)

Current vectors are placed head to tail to show the path a particle would have traveled in a perfectly homogeneous flow.

There are 3 composite progressive vector plots, one for each major depth level. The plot traces begin at the representative mooring location which is represented by a '*' (asterisk symbol), with '+' (plus) symbols along the trace marking each 100 days. Depth 3000 meters shows the data from the three instruments at that depth. Depths 3900 and 4100m each show the traces from the 6 instruments at those levels. Depth 4300m, shows not only the six traces from 4300m but also includes an additional trace from the instrument at 4485 meters which is shown with a thicker line and has circles each 100 days.

There are six 3-dimensional progressive vector plots, one for each mooring. The '*' marks the instrument depth/latitude/longitude position. For reference, a 'shadow' of each progressive vector trace is repeated on the bottom of the plot.

Plots for each individual time series are shown on the 2nd and 3rd fiche in row C. The individual progressive vector plots are annotated at the first of each month.

Statistics (composite and individual)

Statistics of U (eastward velocity), V (northward velocity), and T (temperature) from the filtered time series are included. The equations used to derive the statistical parameters were described by Tarbell et al., 1988. The printed text has a table of statistics from the Gaussian filtered version of the time series.

The statistics for each individual time series were created using the half hour sampled version of the data and the Gaussian filtered series. They are displayed on the 2nd and 3rd fiche in row B.

Variables versus Time (composite and individual)

Each of the individual Variable versus Time pages display the U (east) and V (north) components, a stick plot and a temperature plot. These plots are not shown on the printed pages but are shown on fiche 2 and 3 in row E.

The composite Variables versus Time plots show one type of plot for several different time series on one page. There are 33 plots in this category which are presented on both printed pages and on the first fiche.

Twenty-four of those plots are composite plots by mooring, that is, they display the same type of plot for the data from each instrument on that particular mooring. Fiche 1 row C contains *Vector Stick* and *U and V component* composite plots. Fiche 1 row D contains *Temperature* and *3D Progressive Vector* composite plots.

There are nine composite plots by depth level (3900, 4100 and 4300m.). Each of the depth level plots shows the same type of display for each of the 6 time series at that depth (one display for each mooring). Each of the three depths has three displays (*Vector Sticks*, *Temperature* and *Progressive Vectors* plots).

Vector stick plots versus Time

Because the mean flow of the current is predominately east/west the vector stick displays have been rotated so that 'east' is represented as 'up' and 'north' is left along the plotting axis. The velocity scales may differ for each mooring or for each level to best display the character of the measured currents, but all plots on each page have the same velocity scale.

Temperature versus Time

Temperature values are shown in degrees Celsius. The temperature composite plots may use different scales within the same plot to highlight the temperature activity.

U and V components versus Time

The U (East) and V (North) components are each plotted as individual variables versus time.

Spectral diagrams

Velocity and temperature data are displayed as auto-spectra using the program "Prospect" (Hunt, 1982). The horizontal kinetic energy (HKE) spectrum is half of the sum of the spectra of the east and north components. It has the advantage of not being tied to a particular coordinate system. The spectra are one-sided so that the integral of the spectrum with respect to frequency is equal to the variance of the original record.

The plots are log-log rather than 'variance preserving', that is, the contributions of various frequency bands to the total variance are not in proportion to the displayed areas. The unfiltered data for these calculations was prewhitened and recolored. These calculations were based on one piece with two degrees of freedom.

For plotting, 'Prospect' averages the spectra in increasingly larger groups at the higher frequencies to reduce superfluous points. In Table 8, below, each of the first 40 plotted points represents the average of 3 adjacent frequency bands, the next 15 points each represent the averages of 6 adjacent bands and so forth.

| Table 8 | Spectra frequency-averaging grou | ıps |
|---------|----------------------------------|-----|
|---------|----------------------------------|-----|

| Frequencies | plotted points |
|-------------|----------------|
| 3 | 40 |
| 6 | 15 |
| 15 | 6 |
| 30 | 30 |
| 60 | 15 |
| 150 | 6 |
| 300 | 30 |
| 600 | 4 |
| remainder | 1 |

Data presentation

The first page is a list of the statistics for each time series.

Following the page of statistics are groups of composite plots ordered by mooring. Data from each mooring is displayed using different presentations on 4 consecutive pages. The first page for each mooring contains the velocity vector stick diagrams; the second page contains the temperatures for that mooring. The third page displays the U and V components. The fourth page displays the progressive vector diagrams with the starting points lined up as if on a virtual mooring.

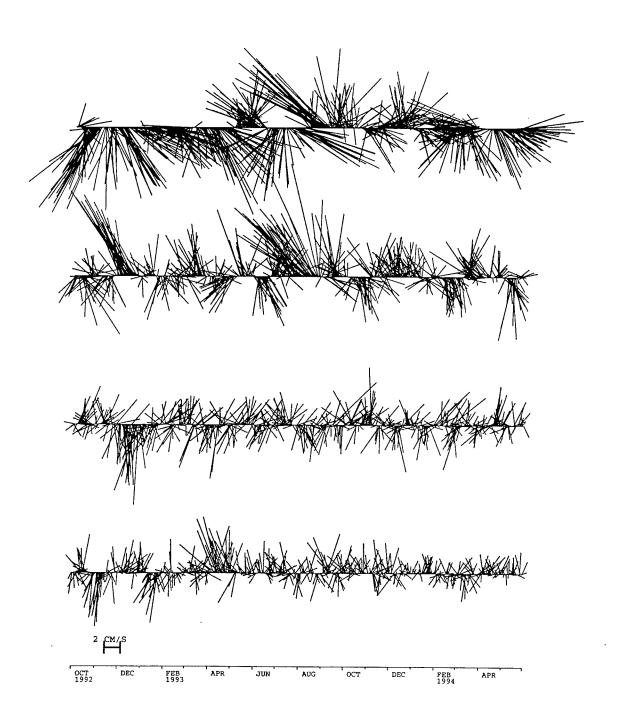

The next 9 pages are composite plots ordered by the 3 major instrument depths (3900m, 4100m, 4300m). For each depth there are composite stick plots, composite temperature plots and 3-dimensional progressive vector plots.

| Current and temperature measurements from Vector Averaging Current Meters (VACMs) deployed from September 1992 to June 1994 as part of the Deep Basin Experiment (DBE) measuring the trans-equatorial water flow are presented. Salinity and temperature measurements from Conductivity/Temperature/Depth (CTD) casts taken during the mooring deployment and recovery cruises are also presented. Six mooring sites were occupied with a total of 24 vector averaging current meters and 4 Aanderaa current meters. Three nominal depths (3900, 4100 and 4300 m.) were occupied on each mooring. Three of the 6 moorings had current meters at additional depths. Basic data from the vector averaging current meters are presented both in statistical tables and graphically as histograms, scatter plots, progressive vector diagrams and spectral diagrams. One day Gaussian filtered plots are shown in composite displays of variables versus time. Temperature and salinity profiles and θ/S plots for 22 CTD stations are presented. | | | | | |
